	The Establishment of a Training Materials Base
	for Special Training in Missile Regiments
	The modern missile weapon is a complex of diverse and complicated equipment, mechanisms, and assemblies, created as a result of the latest achievements in a whole series of scientific and technical fields.
	The complexity of the equipment, the high demands for precision in its manufacture, and the great stability of the parameters, given by the basic instruments all this has a definite impact on the operation of missile complexes.
	The process of preparing missiles for launching is very complicated, protracted, and completely taken up with different operations, the performance of which demands great skill and attentive and laborious work by the personnel. The slightest negligence by any member of the crew who does not possess sufficient skill at his work may lead, at best, to a delay in the launching of the missile. Therefore, the designers are confronted with the task of simplifying to the maximum the technology of preparing missiles for launching.
	The inadmissibility of a violation of the instructions during the performance of technological operations, and even more, of breakage of materiel and of the putting out of commission of expensive instruments and assemblies, and, at the same time, the demands for high speed in the work of preparing missiles for launching, imposes great responsibility for his own sector of the work on each member of a crew. Therefore, the operation of missile equipment, which constitutes most of the everyday combat work of subunits, is impossible without the appropriate special training of the personnel.
·	In many cases, missile units are reinforced with officers who have no previous training in missile specialties. Officers who have completed courses of short duration at higher educational institutions and at industrial enterprises must constantly renew and increase their

	knowledge directly in missile regiments.  Thorough knowledge of the material, of the physical nature of processes and phenomena which take place during the work of the ments, units, and assemblies and a knowledge of the procedure and for preparing them for work are needed, not only by the officers, also by the enlisted men and noncommissioned officers. The latter have the requisite knowledge, both of their own sector of work at those allied to it. These requirements are imposed because, first all, an officer is not able to check the correctness of all the technological operations carried out by the crew members constant and secondly, because in the organic structure of subunits it is times necessary to replace engineers by technicians and technician enlisted men and noncommissioned officers (in secondary sectors in addition, enlisted men and noncommissioned officers who have acquired thorough knowledge and experience in working with the emay quickly lose these skills after their demobilization from the which will undoubtedly have an adverse effect on the preparedness reserve cadres. Therefore, missile units, even in peacetime, must	i rules but er must ed of st of  tly; some- ens by of work). not quipment e army, s of
	come a school for the special training of personnel.  This task can only be accomplished by having a complete trainaterials base in missile regiments which fully supports the not course of combat training.	ining rmal V
	Experience shows that a good training materials base, even has no organic equipment (vooruzheniye) at all, allows the train personnel in the use of equipment in a sufficiently short period (this is very important in the formation of military units befor receive new types of missile equipment).	of time
	The training base ensures deeper study of the materiel by p and helps them to acquire practical skills in work with materiel turn, work with training equipment excludes the possibility of t mature exhaustion of resources of equipment and also of breakage faults and of the putting out of commission of the various assem a combat missile.	. diagrams on the blackboard. Posters allow the internal mechanism of devices and assemblies to be shown.  Posters depict the most important diagrams, schedules, tables and complicated instruments and mechanisms, and their separate parts, details, and components. Posters should be prepared in several colors. The use of several colors, as a rule, increases the clarity of the training aids and simplifies assimilation of the training material.  It is necessary to have posters showing the structure of all the assemblies of the missile complex, and—when organic equipment is not available—the general appearance of the separate assemblies, control panels (pult), etc., as well.  Electrified diagrams (stands). In order to simplify the study of complex electric, electronic, kinematic, hydraulic, or pneumo-hydraulic diagrams of instruments and systems, electrical lighting of the basic elements of a diagram is normally used. The switching of the lighting in order, as the elements are worked through, may be carried out both manually and automatically by means of time mechanisms and relays incorporated in the lighting circuit.  By improving the lighting circuit and by introducing additional automatic units, it is possible to achieve the visual representation of the workings of such processes as the flow of liquids in pipelines, the movement of mechanisms, burning, etc. Although the production of electrified stands is difficult and takes up a lot of time, they justify themselves, because they help with the better assimilation of the material which is being studied. Mock-ups and models. In order to demonstrate the structure and working principles of the main instruments, mechanisms and assemblies of missile equipment, mock-ups and models are prepared. These may be in one plane, built up on panels, or three-dimensional (obyemnyy), and static or working.	
Mock-ups and models are indispensable in the absence of cross- sections of actual elements of equipment. It is probably impossible to give a better demonstration of how a type of mechanism works, or of the coordination of its parts while it is working with any equip- ment other than working mock-ups and models.	
Working mock-ups and models may be used not only to show the work of individual instruments and mechanisms, but also to demonstrate coordination in the work of several assemblies (for example, the coordination of the pad (stol), carrier (telezhka), and erector (ustanovshchik) in the installation of the missile on the launching pad, etc.).	e
Specialized training aids (trenazher). Training aids are constructed for the carrying out of separate technological operations and to impart practical working skills to personnel.	
In their purpose, construction, and complexity, training aids may vary quite widely. Training aids range from the very simple (for example, the device for training in the plugging in of connector (podklyucheniye shtepselnykh razyemov) and fueling hoses) to the very complicated (for example, the trainer for \( \sqrt{5} \) to 7 words missing \( \sqrt{pad} \)	,
Training aids should be created for the mastery of such operation and work as the adjustment (nastroyka) of pressure regulators (redukt davleniya), the adjustment of the throttles (drossel) of the system for emptying the tanks, the installation of the powder charge ignition (pirozazhigatelnyy) device, checking the resistance of the insulation checking the powder squibs (pirozapal), checking the pressurization (germetichnost), adjusting the automatic range controls (avtomat upravleniya dalnostyu) checking the gyroscope devices (giropribor), laying the cable network (razvertyvaniye kabelnoy seti) at the technical and launch sites, etc.	or n

	is reviewed. The equipment of classes in each individual case of on a whole series of factors the organic structure of the subfor example, on the availability of training equipment, on the rand size of rooms set aside for the classes. The number of trait classes must always provide for the normal progress of the comba training of all subunits.	epends units, umber ning
	Diagrams, posters, tables, and panels must be of such a siz that the parts and texts shown on them are visible from all the in the classroom. Sketches drawn on paper should be pasted on c board or on cheesecloth for durability. Posters which are to be must be equipped with special loops or rings.	seats ard-
	In all training classrooms it is advisable to arrange devic hanging posters on the walls or on stands.	es for
	For the demonstration of small elements, for example, electricities, automatic equipment of a propulsion system, or of flat models, panels are prepared. Large or heavy instruments, assemble and mock-ups are stored in the classrooms on stands or supports.	
	In the preparation of training equipment (regardless of its the possibility should be considered that some changes in its str ture without basic rebuilding, may be necessary, as should the feasibility of partial disassembly for transportation, and of but the equipment from available (not scarce) materials.	ruc-
	Training equipment must not only completely represent the subut should also be attractively and well made up, because well produced stands, posters and training aids increase the interest of pupils in the subject being studied. However, improving the stand of preparation does not at all mean that it is necessary to instandant massive stands and supports finished in rare varieties of wood. pensive construction in equipment may be justified to a certain extent for study rooms and auditoriums in institutions of higher learning, but not for classes in units. Such stands need a great expenditure of forces and means, which often far exceeds the cost	the dard 11 Ex-
	the mock-up or diagram itself.	50X1-Hl
l l		

The basic requirement made of training equipment is that it should ensure the maximum intelligibility of the material being studied. When preparing the equipment, this requirement should not be forgotten. If, for example, in an automatic electrified diagram, the possibility of stopping it at a given operation is not foreseen, or the possibility of independent (separate) illumination of its elements, if a diagram is prepared on a dark background, without clear listing of the elements using acceded terminology, then the diagram may lose its value as a training aid to a significant degree.

The greatest difficulty in setting up a training materials base will be presented by the development and preparation of working models, electrified diagrams and training aids. Technical guides to the preparation of this equipment consist mainly of technical and operating documentation, describing and directing the work of the respective missile equipment assemblies. For example, electrified diagrams of the respective systems are drawn on a large scale, and for clarity certain additions are introduced (different colors for individual elements, relief, etc.). The installation of electrical illumination depends on the purpose and the availability of the various automatic elements of the diagram being prepared. Thus, the design collective of units must be able to carry out the development and preparation of similar diagrams without any additional documentation.

The activities of the design groups, of rationalizing and inventing collectives in the regiments must at present be directed mainly toward the solution of the main task of supplying training materials bases with special training aids.

As has already been said above, the technological process of preparing a missile for launching consists of a large number of different operatives, for the correct and rapid fulfillment of which a good standard of training is needed in the personnel. For this, the best training aids will be actual examples of missile equipment, but in practice, the requirement for the high combat readiness of material and for the preservation of its resources excludes the possibility of frequent training with it. Additional training of personnel must be carried out on specialized training aids.

Specialized training aids cannot be examined in isolation from other types of training equipment. It is sufficient, for example, to put the elements for controlling the illumination of the electrified hydraulic and electrical diagrams of the fuel servicer on a separate panel, arranging them in the same order as in an actual assembly, and one has a training aid which will permit the members of the crew to perfect the work of fueling. The same applies to the working model of an erector. An electrified pneumo-hydraulic diagram of the missile will make an original training aid if the possibility of simulating prelaunch preparation is taken into consideration during its construction.

In order that a crew member, working with a training aid, can follow the results of his actions, it is advisable to develop training aids which are combined with electrified diagrams and working mock-ups. In training aids which are being set up it is essential to foresee the possibility of having the instructor artificially introduce various malfunctions, in order to train the personnel in their quick detection and correction.

Thus, for non-organic design organizations and for the rationalizing and inventing collectives of missile regiments the field of activity in the problems of development and preparation of training aids is very wide.

In setting up a training materials base, the problem of finding materials for the preparation of training equipment assumes a special place. Elements and assemblies of missiles which are of obsolete construction and aircraft equipment, delivered to units for mounting by classes, are a big help in the preparation of training aids.

For most samples of equipment only general commercial materials are needed, but for some samples elements in short supply are used-relays, timing mechanisms, small electrical motors and other elements of automation, which are general purpose products and are not produced at missile equipment enterprises. Attention should be drawn to the initiative of certain unit commanders, who managed to organize the receipt of sub-standard (nekonditsionnyy) production samples (relays, electric motors, etc.) from enterprises of the electrical industry, located close to their disposition areas.

	50X1-HUM
Part of the equipment of training classes (from the list given above), intended for manufacture by the forces of regiments, was entered in the Table of Norms for the Supply of Military Training Equipment to Units of the Missile Troops (Tabel norm snabzheniya voyenno-uchebnym imushchestvom chastey raketnykh voysk). Materials in short supply will be supplied by the Chief Engineering Directorate of the Missile Troops (Glavnoye inzhenernoye upravleniye raketnykh voyskGIURV) on application by units.	
The Table of Norms for the Supply of Military Training Equipment envisages the preparation of the following equipment at the repair factories of the Chief Directorate of Missile Troop Equipment (Glavnoye uprovleniye raketnogo voyskovogo oborudovaniyaGURVO) and its supply to units:	,
training aids for carrying out the pneumatic testing of a missile;	
training aids for carrying out independent and complex testing of the control system;	
training aid stands on the oxidizer servicer;	
training aid stands on the fuel servicer;	
training aid stands on the erection of a missile on a launch pad.	
Some of the samples of this equipment are already prepared at troop units and handed over for adaptation and perfection to the repair factories of GURVO, and part is still being developed at institutions of higher learning and in troop units in accordance with subjects of scientific research which have been assigned. But these are only the first steps. It is possible to evolve and prepare all the samples of training equipment, including simple training aids for the perfection of individual operations in the technological process of preparing missiles for launching, with the forces of the design collectives of units.	
In view of the need for the quickest possible equipment of missile troops with high quality training and practice equipment,	
	50X1-HUM

it is advisable to set up a special experimental-design organization, supplying it with an experimental and a production base. Great assistance must be rendered to the units in the evolution and preparation of training equipment by the workers of the directorates and services of the Commander-in-Chief of the Missile Troops.

In certain missile regiments, the construction of training buildings to house the special training classes is being carried out with initiative. This is a very good start. It is advisable to encourage this initiative in every way.

The constant exchange of experience of work and of periodic information about achievements in setting up a training materials base is also not unimportant.

The commanders and political workers of large units and units are responsible for setting up a model training materials base for special training. However, there have been some cases in which commanders of regiments who did not have a training materials base, on receiving instructions on the establishment of a non-organic design bureau, have limited themselves to writing into the instructions the names of several officers who have entered the composition of these bureaus.

In their content, composition, and work, non-organic design bureaus must conform with their designation. The preparation of training aids greatly facilitates the improvement of the special training of those who are to carry out the work directly. It is necessary to bring the most skilful craftsmen (master) and handy men (umelets) from among the enlisted men and noncommissioned officers into the design bureaus. The design bureaus must be supported with all means, material and tools, and special premises and a production base must also be allotted to them, even at the expense of existing repair shops. Specific tasks with time limits for their performance and for the preparation of this or that sample of training equipment, should be assigned to the design bureaus after the status of the training materials base has been clarified and after the availability of means and materials has been determined.

It is necessary to search more persistently and locally for all the ways and means to combat this task, directing Party and Komsomol organizations toward its accomplishment, and enlisting the whole group spirit of units.
